

PYTHON MODULE RESEARCH:

Some notable examples are as follows: matplotlib, pandas, or **OpenCV**

OpenCV is a library that connects the real-world environment with the brain of a stateless electronic device. This implies that the growth of optimizations and resolving pressing issues can be readily paired with software programs such as the Python language's hailed library: OpenCV. Much like OpenAI, the classical (non-deep-learning) computer vision algorithms are open source and play a huge role in artificial intelligence and other engineering trends.

Leveraging the tool made available by the Python language is a double-edged sword. According to a study done by columnist Doctor Waelen who has studied at the University of Twente in the Netherlands, computer vision is often tied to deep learning initiatives to develop effective models. Otherwise known as "big data," these datasets must be stored and trained in large data centers where negative environmental impacts are inevitable. Notably, the high water and energy consumption of energy surges in relation to the quality of what is produced by each computation cycle.

However, an aforementioned idea highlights that the standard computational approaches utilised by OpenCV and other image processing and analysis instruments are denoted as "non-deep-learning".
